So does the Pixel 9/10 series actually support true bypass charging? Seeing conflicting info.

I just picked up the Pixel 10 and I'm trying to figure out the best way to preserve battery health. I would like to know if its actually beneficial to leave this thing plugged in all day?

I've been digging through threads on reddit about bypass charging, and I'm seeing mixed results on whether the Pixel 9/10 supports true bypass charging (where the phone runs purely off the wall power) or if it's just a software trick.

For instance, [this comment](#) suggests it might be a "pseudo bypass" where basically just aggressive trickle charging limits rather than physically disconnecting the battery. This [other comment](#) seem add on to say its impossible due to the Pixel's hardware.

I've done some testing myself using the "Device Info HW" app and I do notice it stays "Not charging" for a good while, maybe a minute or two, and then it switches to "Charging." Interestingly, the charging level on the app shows 79% when this happens, as opposed to the system battery icon which still shows 80% with the shield. (For context, I am using a 20W charger).

If it's just "pseudo" bypass, would leaving it plugged in still add cycles/wear?

Trying to decide if I can leave it plugged 24/7

A lot of hearsay from random articles and no official statement on Google websites. It does not have it.

Few people seem to test it. Use a USB power meter for \$15 from Amazon. While actively using your Pixel 10, it will show 0 watts when it is at 80% limit. Once it drops to 79%, your phone charges again.

Few phones have full bypass charging, but iPhones and many Samsung phones will draw outlet power to minimize charging. Samsung also has game mode on some models to toggle full bypass charging.

You tested already? Do you happen to have these tests? I am curious.. I am trying to figure why it doesn't explain the article tests although they did use software to test the voltage as opposed to a power meter..

From what I can see and contrary to what some articles say, as soon as something is not physically disconnected from power sources, there will always be small amounts of energy traveling through to everything that is inside your phone (battery included). An example would be the charger plugged into your power outlet. Nothing is connected on the other end, no phone, no device, yet, there's still trickle energy lost travelling into the charger plug.

Unless there's a physical switch mechanic, your battery always receives a minimum amount of energy, albeit extremely small.

I tried to figure out the same thing months ago and came to no real consensus, in my opinion. I concluded myself that it does not have it, but what do I know

Pixel 6a Pixel 3a

On pixels you don't get to control bypass mode. it will automatically trigger during certain conditions when you have limits set. google has not shared specific conditions though so it's hard to say what triggers it but adaptive charging triggers it way more than limit charging afai.

Create

activate bypass. PD only chargers will just very aggressively limit trickle.
